

Practical Session Week-7

Assembly Programming

Using intrinsic functions in C/C++

Objectives.

1. To write C++ programs using Intel SSE intrinsics.
2. To write C++ programs using Intel AVX intrinsics

Tasks.

1. Download '*source.cpp*' file from DLE. Open Visual studio in Windows and create an empty CPP project. Copy paste the code of *source.cpp* in your project. This code contains the implementation of matrix-vector multiplication (MVM) algorithm using
a) normal C++ code, b) SSE intrinsics, c) AVX intrinsics.
 - a. Build and run just ***MVM_default()*** routine. Measure the execution time. It is important to note that for an accurate measurement, the execution time needs to be at least some seconds. Thus, given that the execution time of the current routine is lower than 1sec at all times, we run it 't' times and then the overall execution time is divided to t (the value of 't' iterator needs to be appropriately defined).
 - b. Build and run just ***MVM_SSE()*** routine. Measure the execution time.
 - c. Build and run just ***MVM_AVX()*** routine. Measure the execution time.
 - d. Compare the results.
 - e. Using ***MVM_SSE()*** as a guidance (Matrix-Vector Multiplication algorithm), implement Matrix-Matrix Multiplication algorithm ('*MMM_default*' routine) using SSE intrinsics. All the intrinsics needed are provided in ***MVM_SSE()*** routine.
 - f. Using ***MVM_AVX()*** as a guidance (Matrix-Vector Multiplication algorithm), implement Matrix-Matrix Multiplication algorithm ('*MMM_default*' routine) using AVX intrinsics. All the intrinsics needed are provided in ***MVM_AVX()*** routine.
 - g. Compare the results.
2. Implement FIR algorithm using SSE and AVX intrinsics. A code to start is given in '*FIR_default()*' routine in '*source.cpp*' file
